

Code Testing

The test input is given in file “**input**”. The correct output is given in file “**output**”. Both “**input**” and “**output**” are text files. You can use any text editor (e.g., Sublime) to open them and view the contexts.

To test your code, put “**input**” and “**output**” in the same directory with “**pp1.py**”, and then run it in the Linux terminal using the following command, which generates a text file called “**myoutput**” that contains the output of your program.

```
$ python3 pp1.py > myoutput
```

Then, run the following command in Linux terminal to compare the output of your program and the given output.

```
$ diff output myoutput
```

If there is no output of running **diff**, it means the **output** and **myoutput** are identical. Note that TA will use the same command to test your program.

Hints: If **diff** shows difference exits between the two files, which you cannot with naked eyes, one possibility is that your **myoutput** is generated on Windows while the **output** file I provided is produced on Linux. Since Windows and Linux use different control characters to represent line breaks, there’s always this invisible difference between Windows and Linux files containing multiple lines. So the only solution is to execute your code on Linux to generate the file that contains the output of your program.
